Abstract

Background The general pediatricians and primary physicians sometimes face immense difficulty in referral judgments regarding which infantile hemangiomas (IHs) require referrals and when is the appropriate time to refer IHs for treatment. This resulted in the treatment being delayed beyond IHs' critical timeframe. The Infantile

25 Hemangioma Referral Scores (IHReS) have been recently developed, with the aim to
26 solve this problem.

27 **Objectives** The objective of the present study is to evaluate the reliability of IHReS and
28 to assess the possibility of using this instrument in our country where a similar problem
29 of delaying treatment of IHs is currently existing.

30 **Methods** The present study was a prospective, cross-sectional study. Thirteen selected
31 clinical cases were used to assess the reliability of IHReS among physicians who may
32 have had the chance to deal with IHs patients. The target physicians across the country
33 were asked to participate in the study via an online platform (google forms) to decide
34 whether to refer IHs patients for treatment or observe. There were 3 steps of assessment;
35 step 1) Usual practice evaluation, step 2) Using IHReS, and step 3) Retesting by using
36 IHReS.

37 **Results** Substantial agreement was observed after using IHReS (step2) for interrater
38 reliability, with Fleiss' Kappa values of 0.80 and 0.78 among IHs experts and non-
39 expert physicians, respectively. Regarding repeatability, in the test-retest assessments,
40 Cohen's Kappa coefficient values revealed almost perfect agreement in intrarater
41 repeatability for both experts and non-expert physicians (1.00).

42 **Conclusion** IHReS is a simple, easy to assess tool for non-expert physicians. The
43 benefit in the increase of interrater agreement was found in both IHs experts and non-
44 expert physicians. It has had the reliability to be used in making referral decisions
45 regarding IHs patients for treatment among Thai physicians. Using IHReS can improve
46 clinical outcomes by identifying which patient needs early intervention to minimize the
47 possible complications.

What is Known?

- IHs is a disease with a window of opportunity in which physicians can make timely intervention and prevent poorer outcome. This critical time frame for optimizing outcomes can be missed if there are delays in referral or treatment.
- The heterogeneous presentation of IHs poses a clinical challenge for physicians in determining the need for treatment and subspecialty referral.

What is New?

- IHReS is a simple, easy to assess tool that has reliability to be used to make decisions regarding referral of IHs patients for treatment in both IHs experts and non-expert Thai physicians.
- Using IHReS can improve clinical outcomes by identifying the patients that need early intervention to minimize the possibility of complications.

Key words:

Infantile hemangioma, treatment, refer, score, physician

Abbreviations:

<i>IHs</i>	Infantile Hemangiomas
<i>IHReS</i>	The Infantile Hemangioma Referral Score
<i>HAS</i>	Hemangioma Activity Score
<i>HSS</i>	Hemangioma Severity Scale
<i>HASI</i>	Hemangioma Activity and Severity Index
<i>HDCS</i>	Hemangioma Dynamic Complication Scale

Introduction

Infantile hemangiomas (IHs) is a disease with a window of opportunity that allows timely intervention and prevent poorer outcomes.¹ This critical time frame for optimizing outcomes can be missed if there are delays in referral or treatment. A judgment of whether to refer for treatment or observe IHs is sometimes a difficult decision especially among non-expert physicians. This is due to the unique characteristic of IHs that has its own spontaneous regression over a period of time², thus, most non-expert primary physicians usually provide a main leading advice for those IHs patients to be observed without intervention or treatment. However, some IHs became problematic ones later when they start to have a rapid progression during proliferative phase. Most primary physicians may not able to identify problematic IHs at the time of examination that resulted in the treatment delays.

A similar problem of delayed referral of IHs for treatment is also in occurrence in our country. Most of the general pediatricians and primary physicians face a difficulty in referral judgment to decide which IHs and when is the appropriate time to refer IHs for treatment to avoid the consequence of delayed treatment beyond the critical time frame.

Léaute-Labrière et al. recently proposed Infantile Hemangioma Referral Score (IHReS) as an initial tool for primary physicians to make their decisions to refer patients to expert centers.³ This tool was developed by the experts from 7 different countries across the European countries. It had a high sensitivity of 96.9% which is suited for screening purposes. After IHReS has been published, we all agree that this may be a useful instrument to solve the problem of delayed treatment among IHs patients. Therefore, this became the objective of the present study to evaluate reliability of IHReS and to assess the possibility of using this instrument among Thai physicians.

100 **Methods**

101 **Data collections**

102 This was a prospective, cross-sectional study conducted in Thailand. Thirteen
103 selected clinical cases were used to assess reliability of IHReS among physicians who
104 may have had the chance to deal with IHs patients. The target population; pediatric
105 dermatologists, general pediatricians and primary physicians across the country were
106 asked to participate the study via online platform (google forms). Individual participant
107 gave consent to the study by replying back the online questionnaire.

108 The participants were asked to make a decision whether to refer for treatment or
109 observe individual 13 selected clinical cases provided with a clear high-quality image
110 with essential history and physical examination. Three steps of the study intervention
111 were designed; step 1) Usual practice assessment of the selected clinical cases without
112 reference to the IHReS, step 2) Completion of the IHReS questionnaires of the same
113 selected clinical cases, and step 3) Completion of the IHReS questionnaires for a second
114 time (test-retest) one week after. The authors attached IHReS together with selected
115 clinical cases via the google forms, thus, all participants were able to make a decision
116 and submit their answer in one step. We used a personal code that was created
117 individually by each participant to match the answer in step 3 which were made a week
118 later, with the previous answers in step 1 and 2.

119 The number of the target population in the study were calculated from the
120 determination of sample size for estimating proportions with expected agreement of 0.8
121 with the margin of error of 0.1. For a confidence level of 95%, α was set at 0.05 and the
122 critical value was 1.96. This resulted in a total calculated participant requirement of at
123 least 62 participants.

124 **Statistical methods**

At the end of the study, the collected data were analyzed using STATA software version 10 (StataCorp LP). Descriptive statistical methods - means, standard deviations (SDs), medians, and frequencies were used to analyze the demographic data. Internal consistency was calculated by using Cronbach's alpha. The Fleiss' Kappa was used to test interrater agreement, while the Cohen's Kappa coefficient was used to analyzed agreement of the repeatability decisions (intrarater agreement). Statistical significance was set at $P < 0.05$.

Patient and public involvement

Patients or the public were not involved in the design, or conduct, or reporting, or dissemination plans of our research.

Results

A total of 94 questionnaires were sent out to the target population; pediatric dermatologists, general pediatricians and primary physicians across the country via online platform (google forms), and with 68 (72.34%) were returned. There were 28 primary physicians, 36 general pediatricians, and 4 pediatric dermatologists participated. The majority of participants (56 physicians, 82.36%) were experienced in treating IHs patients, eight physicians (11.76%) have never had the experience in treating this condition, and four pediatric dermatologists (5.88%) were the IHs experts. Sixty-four (94.12%) participants have not known IHReS before participating in the study.

There were 13 selected clinical cases of IHs in the present study. Internal consistency tested by Cronbach's alpha revealed a value of 0.88. The participants were classified into two groups, the IHs expert group (4 pediatric dermatologists) and the non-expert group (64 participants: 28 primary physicians and 36 general pediatricians). Sixty-eight participants completed the step 1 and 2 questionnaires. The decision made at

step 1 (usual practice assessment without IHReS) revealed moderate agreement for interrater reliability in IHs experts, while the fair agreement was observed in non-expert physicians, Fleiss' Kappa values = 0.42 and 0.23 respectively, Table 1.

For both expert and non-expert physicians, there were substantial agreement for interrater reliability at step 2 (completion of the IHReS questionnaires); Fleiss' Kappa values = 0.80 and 0.78, and almost perfect agreement was observed for interrater reliability in both groups, with Fleiss' Kappa values for step 3 (IHReS retesting) of 0.87 and 0.81, respectively. Table 1 shows the steps of the study interventions and the agreement results in IHs experts and non-expert physicians.

Regarding repeatability, in the test-retest assessment, Cohen's Kappa coefficient values revealed almost perfect agreement in intrarater repeatability for both IHs experts and non-expert physicians (1.00).

The average time needed to complete IHReS per each case was 12.59 seconds (SD 3.55). A satisfaction survey was sent to all 68 participants. The survey consisted of 4 questions and the value of Cronbach's Alpha for the satisfaction was acceptable, $\alpha = 0.72$. Percentage of participants' satisfactions in 4 different aspects of IHReS are represented in Fig. 2.

Discussion

IHs are commonly encountered in primary care and most often remain asymptomatic, resolving without sequelae. Even though certain characteristics are associated with a greater risk of complications, associated anomalies, and disfigurement, most of non-expert physicians usually provide the main leading advice for those IHs patients to be observed instead of early intervention or treatment. The updated consensus guidelines^{1,2,4-6} had provided a suggestion of early treatment and timely intervention, however, the heterogeneous presentation poses a clinical challenge

for physicians in determining the need for treatment and subspecialty referral. The heterogeneous presentation included patient age⁷, IHs type, different sizes of IHs, numbers of IHs, characteristics, locations, anatomical patterns⁸, revealing of complications, timing of the IHs' growth, and parental preferences. The choice of active non-intervention as the primary approach to uncomplicated lesions were usually made. Life- and function-threatening IHs, as well as IHs associated with a high risk for disfigurement and scarring, necessitate systemic treatment. The major problem for non-expert primary physician is that when is the appropriate time for treatment of each individual case. This problem had become more evident, thus, the development of many IHs scoring systems which aimed to provide an objective and standard measurement for early detection of problematic IHs and as a follow-up tool during the treatment have been developed.

Scoring IHs is challenging because of the heterogeneity of their morphology, behavior, and response to treatment. Many IHs scoring systems have been developed during the past decade. Each scoring system has its own advantages for a variety of purposes. The Hemangioma Activity Score (HAS) was developed to measure proliferative activity of IHs.⁹ This instrument has been used to monitor IHs responses during the treatment.⁹⁻¹¹ The Hemangioma Severity Scale (HSS) and Hemangioma Dynamic Complication Scale (HDCS) were developed shortly after with an objective to measure severity of IHs and the complications of IHs for longitudinal usage.¹² The Hemangioma Activity and Severity Index (HASI) was recently developed with a purpose to combine the proliferative activity score together with the severity index in one unified scoring system.¹³

All mentioned instruments are valid and used to measure disease severity that are needed to substantiate the benefit of therapies for IHs.¹¹ As a utility of triage

purpose, the cutoff values of the HSS of 6 or lower and 11 or higher could be used as a triage tool for propranolol treatment.¹⁴ Another study also revealed the cutoff values of IHs with total HSS scores of 6 or greater should be referred for subspecialty evaluation.¹⁵ As a triage purpose, the HSS may be a useful tool for primary care physicians in identifying high-risk IHs that may benefit from therapy. The HSS is a one-page scale with scoring items that require thorough information to complete the total score. The process is somehow needed to be refined to get to the standard results.

Léaute-Labrière et al. recently developed IHRs as an initial tool for primary physicians to make their decision to refer patients to expert centers.³ This is a two-step easy-to-use tool for non-expert physicians, provided with some drawing pictures indicating striking location and practical notice points in making decisions. This tool is free to use and is available to be downloaded from www.ihscore.com (Fig.1). After IHRs efficacies had been published, we all agree that this may be a useful instrument to solve the delayed treatment among IHs patients. Thus, initiation of the present study was set to evaluate reliability of IHRs and to assess the possibility of using this instrument among Thai physicians.

Our study was conducted in Thailand among the target physicians who deal with IHs patients in their real practices that includes primary physicians, general pediatricians, and pediatric dermatologists. The present study revealed that non-expert physicians had fair agreement interrater (Fleiss' Kappa= 0.23) at step 1 (usual practice assessment), while moderate agreement was observed in IHs experts, Fleiss' Kappa= 0.42. This finding reflected that a problem of timely decision making in treating IHs occurred more often in the nonexpert physicians by the usual assessment without the assisting instruments. However, interrater reliability increased to substantial agreement at step 2 (use of IHRs) in the both groups. The result correlated to the findings in the

validation study of IHRoS in 2020 ³, and also reflected that the use of assisting instrument (IHRoS) can help physicians in making their decision to refer IHs patients for treatment. Our findings revealed that there was an increased in mutual agreement and acceptance after using IHRoS not only among non-expert physicians, the IHs experts also had benefited by the use of this score with an increased interrater reliability, Fleiss' Kappa in IHs experts were 0.42 at step 1, and 0.80 at step 2, respectively. The IHRoS also provided a consistent result after retesting at one week later with almost perfect interrater and intrarater repeatability in both groups, Table 1.

The average time needed to complete IHRoS per each case was 12.59 seconds (SD 3.55). A satisfaction survey was sent to all 68 participants. The survey consisted of 4 questions and the value for Cronbach's Alpha for the satisfaction was acceptable, $\alpha = 0.72$. Percentage of participants' satisfactions in 4 different aspects of IHRoS are shown in Fig. 1.

The study design that was done via the online platform made the authors concerned of the returned questionnaires compliance, thus we decided to limit number of the selected clinical cases in the present study to shorten the time to complete the questionnaires. Therefore, there might be some selection bias of some difficult or controversial clinical cases that affected the decision by usual assessment without IHRoS. However, the findings of discriminate decisions between usual assessments vs. using IHRoS supported the evidence that the triage screening tool for IHs as a decision to refer for treatment is essential.

In summary, IHRoS was a simple, easy to assess tool for non-expert physicians. However, the present study also revealed that this tool is beneficial for IHs experts as well. It took a short duration less than a minute to complete the score and had the reliability to be used to make a decision to refer IHs patients for treatment among Thai

physicians. Using IHReS can improve clinical outcomes by identifying which patient needs early intervention to minimize the possibility of complications.

IHReS

To answer the 6 questions below, tick "Yes" or "No."

Infant's name _____
Age _____
Hemangioma onset ____/____/____
Expert center _____

Complications or potential risk of complications (ulceration, visual compromise, feeding difficulties, stridor) ☐ Yes ☐ No

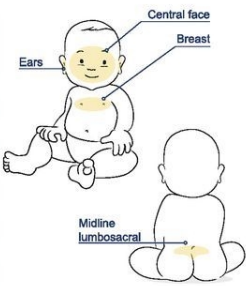

Central face and/or ears ☐ Yes ☐ No

Breast (in girls) ☐ Yes ☐ No

Midline lumbosacral ☐ Yes ☐ No

Size ≥4 cm (focal or segmental) ☐ Yes ☐ No

Number of hemangiomas ≥5 ☐ Yes ☐ No

If at least 1 of the previous situations is ticked "Yes," please refer the patient to an expert center.

If you ticked "No" to all questions, please fill in the table on the next page.

Note: In the case of multiple IHs, the score should be done for each IH.

IHReS

For each parameter, tick "Yes" or "No."

The total score is the sum of the scores from each parameter below.

Parameters	Items	<input type="radio"/> Yes <input type="radio"/> No	<input type="radio"/> Yes <input type="radio"/> No	<input type="radio"/> Yes <input type="radio"/> No	Score Please consider only the highest score for each parameter
Location of hemangioma	Other facial areas than those mentioned previously	<input type="radio"/> Yes <input type="radio"/> No	If yes: 3 points (if no: 0 point)	<input type="radio"/> 3 <input type="radio"/> 2 <input type="radio"/> 0	
	Neck, diaper area, scalp	<input type="radio"/> Yes <input type="radio"/> No	If yes: 2 points (if no: 0 point)		
Size of the biggest hemangioma	≥1 cm on other facial area than those mentioned previously	<input type="radio"/> Yes <input type="radio"/> No	If yes: 3 points (if no: 0 point)	<input type="radio"/> 3 <input type="radio"/> 2 <input type="radio"/> 0	
	2 to 4 cm on other body area than those mentioned previously	<input type="radio"/> Yes <input type="radio"/> No	If yes: 2 points (if no: 0 point)		
Current child age and growth of hemangioma	The infant is <2 months	<input type="radio"/> Yes <input type="radio"/> No	If yes: 3 points (if no: 0 point)	<input type="radio"/> 3 <input type="radio"/> 2 <input type="radio"/> 0	
	The infant is ≥2 and ≤4 months, with an evident growth within the last 2 weeks	<input type="radio"/> Yes <input type="radio"/> No	If yes: 2 points (if no: 0 point)		
Total					

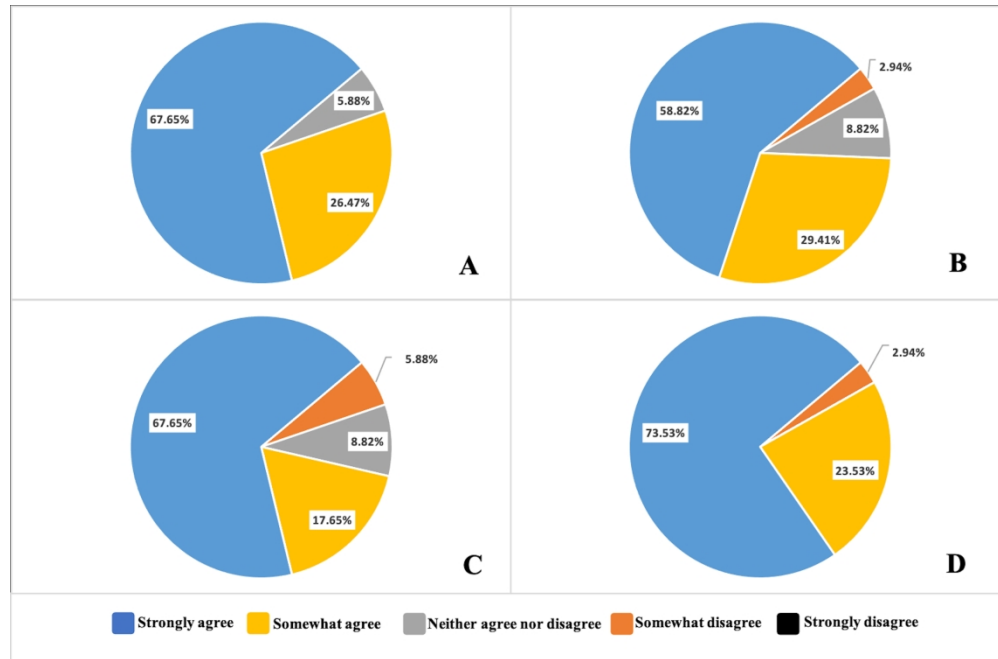

Score ≥4: please refer the patient to an expert center.

Score <4: the patient is not to be referred and should be monitored. The score will be done at every visit.

The final decision to refer the patient to an expert centre is up to the physician and the parents.

Abstract

Background The general pediatricians and primary physicians sometimes face immense difficulty in referral judgments regarding which infantile hemangiomas (IHs) require referrals and when is the appropriate time to refer IHs for treatment. This resulted in the treatment being delayed beyond IHs' critical timeframe. The Infantile

25 Hemangioma Referral Scores (IHReS) have been recently developed, with the aim to
26 solve this problem.

27 **Objectives** The objective of the present study is to evaluate the reliability of IHReS and
28 to assess the possibility of using this instrument in our country where a similar problem
29 of delaying treatment of IHs is currently existing.

30 **Methods** The present study was a prospective, cross-sectional study. Thirteen selected
31 clinical cases were used to assess the reliability of IHReS among physicians who may
32 have had the chance to deal with IHs patients. The target physicians across the country
33 were asked to participate in the study via an online platform (google forms) to decide
34 whether to refer IHs patients for treatment or observe. There were 3 steps of assessment;
35 step 1) Usual practice evaluation, step 2) Using IHReS, and step 3) Retesting by using
36 IHReS.

37 **Results** Substantial agreement was observed after using IHReS (step2) for interrater
38 reliability, with Fleiss' Kappa values of 0.80 and 0.78 among IHs experts and non-
39 expert physicians, respectively. Regarding repeatability, in the test-retest assessments,
40 Cohen's Kappa coefficient values revealed almost perfect agreement in intrarater
41 repeatability for both experts and non-expert physicians (1.00).

42 **Conclusion** IHReS is a simple, easy to assess tool for non-expert physicians. The
43 benefit in the increase of interrater agreement was found in both IHs experts and non-
44 expert physicians. It has had the reliability to be used in making referral decisions
45 regarding IHs patients for treatment among Thai physicians. Using IHReS can improve
46 clinical outcomes by identifying which patient needs early intervention to minimize the
47 possible complications.

What is Known?

- IHs is a disease with a window of opportunity in which physicians can make timely intervention and prevent poorer outcome. This critical time frame for optimizing outcomes can be missed if there are delays in referral or treatment.
- The heterogeneous presentation of IHs poses a clinical challenge for physicians in determining the need for treatment and subspecialty referral.

What is New?

- IHReS is a simple, easy to assess tool that has reliability to be used to make decisions regarding referral of IHs patients for treatment in both IHs experts and non-expert Thai physicians.
- Using IHReS can improve clinical outcomes by identifying the patients that need early intervention to minimize the possibility of complications.

Key words:

Infantile hemangioma, treatment, refer, score, physician

<i>HAS</i>	Hemangioma Activity Score
<i>HSS</i>	Hemangioma Severity Scale
<i>HASI</i>	Hemangioma Activity and Severity Index
<i>HDCS</i>	Hemangioma Dynamic Complication Scale

Introduction

Infantile hemangiomas (IHs) is a disease with a window of opportunity that allows timely intervention and prevent poorer outcomes.¹ This critical time frame for optimizing outcomes can be missed if there are delays in referral or treatment. A judgment of whether to refer for treatment or observe IHs is sometimes a difficult decision especially among non-expert physicians. This is due to the unique characteristic of IHs that has its own spontaneous regression over a period of time², thus, most non-expert primary physicians usually provide a main leading advice for those IHs patients to be observed without intervention or treatment. However, some IHs became problematic ones later when they start to have a rapid progression during proliferative phase. Most primary physicians may not able to identify problematic IHs at the time of examination that resulted in the treatment delays.

A similar problem of delayed referral of IHs for treatment is also in occurrence in our country. Most of the general pediatricians and primary physicians face a difficulty in referral judgment to decide which IHs and when is the appropriate time to refer IHs for treatment to avoid the consequence of delayed treatment beyond the critical time frame.

Léaute-Labrière et al. recently proposed Infantile Hemangioma Referral Score (IHReS) as an initial tool for primary physicians to make their decisions to refer patients to expert centers.³ This tool was developed by the experts from 7 different countries across the European countries. It had a high sensitivity of 96.9% which is suited for screening purposes. After IHReS has been published, we all agree that this may be a useful instrument to solve the problem of delayed treatment among IHs patients. Therefore, this became the objective of the present study to evaluate reliability of IHReS and to assess the possibility of using this instrument among Thai physicians.

100 **Methods**

101 **Data collections**

102 This was a prospective, cross-sectional study conducted in Thailand. Thirteen
103 selected clinical cases were used to assess reliability of IHReS among physicians who
104 may have had the chance to deal with IHs patients. The target population; pediatric
105 dermatologists, general pediatricians and primary physicians across the country were
106 asked to participate the study via online platform (google forms). Individual participant
107 gave consent to the study by replying back the online questionnaire.

108 The participants were asked to make a decision whether to refer for treatment or
109 observe individual 13 selected clinical cases provided with a clear high-quality image
110 with essential history and physical examination. Three steps of the study intervention
111 were designed; step 1) Usual practice assessment of the selected clinical cases without
112 reference to the IHReS, step 2) Completion of the IHReS questionnaires of the same
113 selected clinical cases, and step 3) Completion of the IHReS questionnaires for a second
114 time (test-retest) one week after. The authors attached IHReS together with selected
115 clinical cases via the google forms, thus, all participants were able to make a decision
116 and submit their answer in one step. We used a personal code that was created
117 individually by each participant to match the answer in step 3 which were made a week
118 later, with the previous answers in step 1 and 2.

119 The number of the target population in the study were calculated from the
120 determination of sample size for estimating proportions with expected agreement of 0.8
121 with the margin of error of 0.1. For a confidence level of 95%, α was set at 0.05 and the
122 critical value was 1.96. This resulted in a total calculated participant requirement of at
123 least 62 participants.

124 **Statistical methods**

At the end of the study, the collected data were analyzed using STATA software version 10 (StataCorp LP). Descriptive statistical methods - means, standard deviations (SDs), medians, and frequencies were used to analyze the demographic data. Internal consistency was calculated by using Cronbach's alpha. The Fleiss' Kappa was used to test interrater agreement, while the Cohen's Kappa coefficient was used to analyzed agreement of the repeatability decisions (intrarater agreement). Statistical significance was set at $P < 0.05$.

Patient and public involvement

Patients or the public were not involved in the design, or conduct, or reporting, or dissemination plans of our research.

Results

A total of 94 questionnaires were sent out to the target population; pediatric dermatologists, general pediatricians and primary physicians across the country via online platform (google forms), and with 68 were returned. There were 28 primary physicians, 36 general pediatricians, and 4 pediatric dermatologists participated. The majority of participants (56 physicians) were experienced in treating IHs patients, eight physicians have never had the experience in treating this condition, and four pediatric dermatologists were the IHs experts. Sixty-four participants have not known IHReS before participating in the study.

There were 13 selected clinical cases of IHs in the present study. Internal consistency tested by Cronbach's alpha revealed a value of 0.88. The participants were classified into two groups, the IHs expert group (4 pediatric dermatologists) and the non-expert group (64 participants: 28 primary physicians and 36 general pediatricians). Sixty-eight participants completed the step 1 and 2 questionnaires. The decision made at step 1 (usual practice assessment without IHReS) revealed moderate agreement for

interrater reliability in IHs experts, while the fair agreement was observed in non-expert physicians, Fleiss' Kappa values = 0.42 and 0.23 respectively, Table 1.

For both expert and non-expert physicians, there were substantial agreement for interrater reliability at step 2 (completion of the IHReS questionnaires); Fleiss' Kappa values = 0.80 and 0.78, and almost perfect agreement was observed for interrater reliability in both groups, with Fleiss' Kappa values for step 3 (IHReS retesting) of 0.87 and 0.81, respectively. Table 1 shows the steps of the study interventions and the agreement results in IHs experts and non-expert physicians.

Table 1. The steps of the study interventions and the agreement results in IHs experts and non-expert physicians.

	Step 1 Usual practice assessment	Step 2 Completion of the IHReS questionnaire	Step 3 Completion of the IHReS questionnaire a second time (Test-Retest)	
Statistical measurement	Interrater agreement (Fleiss' Kappa)	Interrater agreement (Fleiss' Kappa)	Interrater agreement (Fleiss' Kappa)	Intrarater agreement (Cohen's Kappa)
IHs Experts	0.42	0.80	0.87	1
Nonexpert physicians	0.23	0.78	0.81	1

Regarding repeatability, in the test-retest assessment, Cohen's Kappa coefficient values revealed almost perfect agreement in intrarater repeatability for both IHs experts and non-expert physicians (1.00).

Table 2. The participants' satisfaction of IHReS in different aspects

The participants' satisfaction of IHReS in different aspects	Number of participants (N)					Total
	Strongly agree	Somewhat agree	Neither agree nor disagree	Somewhat disagree	Strongly disagree	
• IHReS helps in making decision to refer IHs patients for treatment	46	18	4	0	0	68
• IHReS is an easy-to-use tool	40	20	6	2	0	68
• IHReS shortens the duration in decision making process	46	12	6	4	0	68
• Physicians will use IHReS to make decisions to refer IHs patients in the future	50	16	0	2	0	68
Total	182	66	16	8	0	272

The average time needed to complete IHReS per each case was 12.59 seconds (SD 3.55). A satisfaction survey was sent to all 68 participants. The survey consisted of 4 questions and the value of Cronbach's Alpha for the satisfaction was acceptable, $\alpha = 0.72$. Percentage of participants' satisfactions in 4 different aspects of IHReS are represented in Table 2.

Discussion

IHs are commonly encountered in primary care and most often remain asymptomatic, resolving without sequelae. Even though certain characteristics are associated with a greater risk of complications, associated anomalies, and disfigurement, most of non-expert physicians usually provide the main leading advice for those IHs patients to be observed instead of early intervention or treatment. The updated consensus guidelines^{1,2,4-6} had provided a suggestion of early treatment and timely intervention, however, the heterogeneous presentation poses a clinical challenge for physicians in determining the need for treatment and subspecialty referral. The

heterogeneous presentation included patient age⁷, IHs type, different sizes of IHs, numbers of IHs, characteristics, locations, anatomical patterns⁸, revealing of complications, timing of the IHs' growth, and parental preferences. The choice of active non-intervention as the primary approach to uncomplicated lesions were usually made. Life- and function-threatening IHs, as well as IHs associated with a high risk for disfigurement and scarring, necessitate systemic treatment. The major problem for non-expert primary physician is that when is the appropriate time for treatment of each individual case. This problem had become more evident, thus, the development of many IHs scoring systems which aimed to provide an objective and standard measurement for early detection of problematic IHs and as a follow-up tool during the treatment have been developed.

Scoring IHs is challenging because of the heterogeneity of their morphology, behavior, and response to treatment. Many IHs scoring systems have been developed during the past decade. Each scoring system has its own advantages for a variety of purposes. The Hemangioma Activity Score (HAS) was developed to measure proliferative activity of IHs.⁹ This instrument has been used to monitor IHs responses during the treatment.⁹⁻¹¹ The Hemangioma Severity Scale (HSS) and Hemangioma Dynamic Complication Scale (HDCS) were developed shortly after with an objective to measure severity of IHs and the complications of IHs for longitudinal usage.¹² The Hemangioma Activity and Severity Index (HASI) was recently developed with a purpose to combine the proliferative activity score together with the severity index in one unified scoring system.¹³

All mentioned instruments are valid and used to measure disease severity that are needed to substantiate the benefit of therapies for IHs.¹¹ As a utility of triage purpose, the cutoff values of the HSS of 6 or lower and 11 or higher could be used as a

208 triage tool for propranolol treatment.¹⁴ Another study also revealed the cutoff values of
209 IHs with total HSS scores of 6 or greater should be referred for subspecialty
210 evaluation.¹⁵ As a triage purpose, the HSS may be a useful tool for primary care
211 physicians in identifying high-risk IHs that may benefit from therapy. The HSS is a one-
212 page scale with scoring items that require thorough information to complete the total
213 score. The process is somehow needed to be refined to get to the standard results.

214 Léaute-Labrière et al. recently developed IHReS as an initial tool for primary
215 physicians to make their decision to refer patients to expert centers.³ This is a two-step
216 easy-to-use tool for non-expert physicians, provided with some drawing pictures
217 indicating striking location and practical notice points in making decisions. This tool is
218 free to use and is available to be downloaded from www.ihscore.com (Fig.1). After
219 IHReS efficacies had been published, we all agree that this may be a useful instrument
220 to solve the delayed treatment among IHs patients. Thus, initiation of the present study
221 was set to evaluate reliability of IHReS and to assess the possibility of using this
222 instrument among Thai physicians.

223 Our study was conducted in Thailand among the target physicians who deal with
224 IHs patients in their real practices that includes primary physicians, general
225 pediatricians, and pediatric dermatologists. The present study revealed that non-expert
226 physicians had fair agreement interrater (Fleiss' Kappa= 0.23) at step 1 (usual practice
227 assessment), while moderate agreement was observed in IHs experts, Fleiss' Kappa=
228 0.42. This finding reflected that a problem of timely decision making in treating IHs
229 occurred more often in the nonexpert physicians by the usual assessment without the
230 assisting instruments. However, interrater reliability increased to substantial agreement
231 at step 2 (use of IHReS) in the both groups. The result correlated to the findings in the
232 validation study of IHReS in 2020³, and also reflected that the use of assisting

instrument (IHReS) can help physicians in making their decision to refer IHs patients for treatment. Our findings revealed that there was an increased in mutual agreement and acceptance after using IHReS not only among non-expert physicians, the IHs experts also had benefited by the use of this score with an increased interrater reliability, Fleiss' Kappa in IHs experts were 0.42 at step 1, and 0.80 at step 2, respectively. The IHReS also provided a consistent result after retesting at one week later with almost perfect interrater and intrarater repeatability in both groups, Table 1.

The study design that was done via the online platform made the authors concerned of the returned questionnaires compliance, thus we decided to limit number of the selected clinical cases in the present study to shorten the time to complete the questionnaires. Therefore, there might be some selection bias of some difficult or controversial clinical cases that affected the decision by usual assessment without IHReS. However, the findings of discriminate decisions between usual assessments vs. using IHReS supported the evidence that the triage screening tool for IHs as a decision to refer for treatment is essential.

In summary, IHReS was a simple, easy to assess tool for non-expert physicians. However, the present study also revealed that this tool is beneficial for IHs experts as well. It took a short duration less than a minute to complete the score and had the reliability to be used to make a decision to refer IHs patients for treatment among Thai physicians. Using IHReS can improve clinical outcomes by identifying which patient needs early intervention to minimize the possibility of complications.

345 available to be downloaded from www.ihscore.com.
346

IHReS

To answer the 6 questions below, tick "Yes" or "No."

Infant's name _____

Age _____

Hemangioma onset ____/____/____

Expert center _____

Complications or potential risk of complications (ulceration, visual compromise, feeding difficulties, stridor)

Central face and/or ears

Breast (in girls)

Midline lumbosacral

Size ≥4 cm (focal or segmental)

Number of hemangiomas ≥5

☐ Yes ☐ No

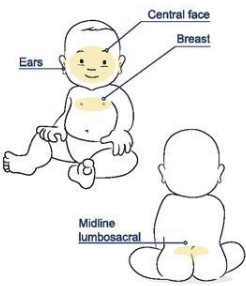

☐ Yes ☐ No

☐ Yes ☐ No

☐ Yes ☐ No

☐ Yes ☐ No

☐ Yes ☐ No

If at least 1 of the previous situations is ticked "Yes," please refer the patient to an expert center.

If you ticked "No" to all questions, please fill in the table on the next page.

Note: In the case of multiple IHs, the score should be done for each IH.

IHReS

For each parameter, tick "Yes" or "No."

The total score is the sum of the scores from each parameter below.

Parameters	Items			Score
				Please consider only the highest score for each parameter
Location of hemangioma	Other facial areas than those mentioned previously	<input type="radio"/> Yes <input type="radio"/> No	If yes: 3 points (if no: 0 point)	<input type="radio"/> 3 <input type="radio"/> 2 <input type="radio"/> 0
	Neck, diaper area, scalp	<input type="radio"/> Yes <input type="radio"/> No	If yes: 2 points (if no: 0 point)	
Size of the biggest hemangioma	≥1 cm on other facial area than those mentioned previously	<input type="radio"/> Yes <input type="radio"/> No	If yes: 3 points (if no: 0 point)	<input type="radio"/> 3 <input type="radio"/> 2 <input type="radio"/> 0
	2 to 4 cm on other body area than those mentioned previously	<input type="radio"/> Yes <input type="radio"/> No	If yes: 2 points (if no: 0 point)	
Current child age and growth of hemangioma	The infant is <2 months	<input type="radio"/> Yes <input type="radio"/> No	If yes: 3 points (if no: 0 point)	<input type="radio"/> 3 <input type="radio"/> 2 <input type="radio"/> 0
	The infant is ≥2 and ≤4 months, with an evident growth within the last 2 weeks	<input type="radio"/> Yes <input type="radio"/> No	If yes: 2 points (if no: 0 point)	
Total				

Score ≥4: please refer the patient to an expert center.

Score <4: the patient is not to be referred and should be monitored. The score will be done at every visit.

The final decision to refer the patient to an expert centre is up to the physician and the parents.
